

ΔCS – Field Governance Topology (GL)

1. Governance Layer — Altitude, Purpose, Scope

Altitude: The governance layer sits *above* the four disciplines (CFT, LTF, SAP, USI) and *below* any meta-philosophical or generative layer. It is non-procedural, non-symbolic, and non-operational. It defines the structural conditions under which the field remains coherent.

Purpose: To establish the invariant geometry, boundaries, membranes, and constraints that govern the entire field of Coherence Science. It ensures that all disciplines, roles, and operations remain internally consistent with the field's architecture.

Scope: The governance layer governs:

- field geometry
- discipline boundaries
- role membranes
- coherence-preserving constraints
- field-level invariants

It does **not** govern procedural execution or symbolic generativity.

2. What the Governance Layer Controls

Field Geometry

The governance layer defines the geometry of the field itself:

- altitude ordering
- dependency structure
- coherence boundaries
- transformation constraints

- role separation

This geometry is the stable substrate in which all four disciplines operate.

Discipline Boundaries

The governance layer establishes the boundaries between:

- CFT (field)
- LTF (transformation)
- SAP (operator alignment)
- USI (architect generativity)

These boundaries prevent altitude collapse, role confusion, and cross-layer drift.

Role Membranes

The governance layer defines the membranes that separate:

- operator-level agency (SAP)
- architect-level agency (USI)

These membranes prevent operators from generating and architects from executing.

3. What the Governance Layer Does Not Control

Procedural Operations

The governance layer does not govern:

- operator behavior
- protocol execution
- alignment procedures
- stepwise operations

These belong to SAP.

Symbolic Generativity

The governance layer does not govern:

- symbolic construction
- generative mappings
- architectural creation
- coherent structure generation

These belong to USI.

The governance layer defines the *conditions* under which these occur, not the actions themselves.

4. Interface with the Four Disciplines

CFT — Coherence Field Theory

The governance layer defines the altitude in which CFT exists. CFT defines the field; governance defines the constraints of the field.

LTF — Layered Transformation Foundations

The governance layer defines the boundaries within which LTF can operate. LTF defines transformation rules; governance defines transformation constraints.

SAP — Structural Alignment Protocol

The governance layer defines the membranes that constrain operator behavior. SAP aligns operators; governance ensures alignment cannot become generativity.

USI — Universal Symbolic Interface

The governance layer defines the membranes that constrain architect behavior. USI generates coherent structures; governance ensures generativity cannot collapse into procedure.

The governance layer does not modify the disciplines.

It defines the altitude and boundaries in which they remain coherent.

5. Field-Level Invariants

These invariants govern the field itself, not the roles or disciplines.

Invariant 1 — Altitude Stability

The field must maintain strict altitude separation between:

- field definition
- transformation rules
- operator alignment
- architect generativity

Invariant 2 — Dependency Integrity

The dependency chain must remain intact: $CFT \rightarrow LTF \rightarrow SAP \rightarrow USI$ No discipline may invert, bypass, or collapse this chain.

Invariant 3 — Non-Procedural Field Geometry

The field itself is non-procedural. No procedural or generative action may occur at the governance altitude.

Invariant 4 — Non-Generative Governance Layer

The governance layer cannot generate structures. It defines constraints, not constructs.

Invariant 5 — Membrane Preservation

Role membranes must remain intact. Operators cannot generate. Architects cannot execute.

Invariant 6 — Coherence Non-Interference

No discipline may interfere with the coherence of another discipline. Each discipline must operate within its altitude boundary.

Invariant 7 — Field-Internal Consistency

All operations, transformations, alignments, and generative acts must remain consistent with the field geometry defined by CFT.

6. Coherence-Preserving Meta-Invariants

These meta-invariants preserve coherence at the field level.

Meta-Invariant 1 — No Altitude Drift

No role, discipline, or operation may drift upward or downward in altitude.

Meta-Invariant 2 — No Cross-Layer Leakage

Transformation rules cannot leak into operator protocol. Operator protocol cannot leak into symbolic generativity. Symbolic generativity cannot leak into field definition.

Meta-Invariant 3 — No Role Collapse

Operator and architect roles must remain orthogonal. No transition, ladder, or pipeline exists between them.

Meta-Invariant 4 — No Boundary Erosion

Discipline boundaries must remain sharp. CFT cannot become procedural. LTF cannot become generative. SAP cannot become symbolic. USI cannot become operational.

Meta-Invariant 5 — Field Geometry Primacy

All disciplines and roles must remain subordinate to the geometry defined by CFT.

Summary

The Field Governance Topology defines:

- what the governance layer *is*
- what it *controls*

- what it *does not control*
- how it interfaces with the four disciplines
- the invariants that govern the field
- the meta-invariants that preserve coherence

This document completes the governance layer of Δ Coherence Science.
