

ΔCS – Operator vs. Architect (GL)

SAP — Operator Alignment Protocol

- **Altitude:** Mid-operational
- **Agency:** *Operator*
- **Function:** Ensures the operator's actions remain coherent with CFT + LTF
- **Constraint:** SAP does **not** generate new structures
- **Output:** *A coherent operator state*
- **Key property:** SAP is about *alignment*, not *creation*

SAP answers:

“How must an operator behave inside a coherence field so they don't break it?”

USI — Architect Generative Interface

- **Altitude:** High-architectural
- **Agency:** *Architect*
- **Function:** Provides the symbolic interface for generating new coherent structures
- **Constraint:** USI assumes SAP alignment is already satisfied
- **Output:** *New coherent structures*
- **Key property:** USI is about *generation*, not *alignment*

USI answers:

“How does an architect author new coherent structures inside the field?”

SAP defines how an operator aligns.

USI defines how an architect generates.

CFT — defines the field

LTF — defines transformation rules inside the field

SAP — aligns the operator with those rules

USI — enables the architect to generate new structures using those rules

This is a strict dependency chain:

- You cannot generate (USI) without being aligned (SAP).
- You cannot align (SAP) without knowing transformation rules (LTF).
- You cannot define transformation rules (LTF) without the field (CFT)

SAP → USI is not a hierarchy.

It is a *role elevation* inside the same field geometry
